(Vivado System Edition)

Communication between the FPGA and uP subsystems

It can be implemented by mean of three different hierarchical levels:

1. Physical

Allows a simple utilization of the resources of the CB as storage elements.

2. Logical

Includes a basic asynchronous logic protocol for a safe utilization of the ComBlock. It requires some reserved areas in the TDPRAM and some reserved registers.

3. Systemic

Implements a high level protocol based on a set of complex instructions for Direct Memory Access (DMA). It provides transparent access from any domain to all resources mapped in a global memory mapping, including those that are not immediately accessible but that are directly accessible from the other domain. It requires a DMA machine in the FPGA, and a corresponding software routine in the uP.

Each level corresponds to a communication layer. Each layer relays on the services offered by the immediate layer below, and provides services that can be used by the layer immediately above.

Resource utilization of the CB in different Devices

•RESOURCE UTILIZATION OF THE CB IN XILINXFPGAS

•RESOURCE UTILIZATION OF THE CB IN ALTERA FPGAS

Family	Name	Slice LUTs	Slice Registers	F7 Muxes	F8 Muxes	Block RAM (kBytes)	Family	Name	ALMs	Logic Registers	Block RAM (kBytes)

Conclusions

- 1. The proposed *Communication Block is* a general purpose and reusable IP which completely absorbs the complexities of the *SoC Interconnection Bus* in modern SoC FPGA devices.
- 2. FPGA and uP subsystems can efficiently communicate through a *ComBlock* without any significant loss in performance and without any penalty in resources utilization.
- 3. Migration of complex systems among different SoC FPGA families and vendors is easier when based on *ComBlocks* since it essentially requires the porting of the *ComBlock* only.
- 4. Most of the uP embedded software and FPGA subsystem designs can be ported with minimal effort, and with facilitated debugging and optimization.
- 5. Since each subsystem deals with the other subsystem by reading and writing in the memory locations of the *ComBlock*, this block provides an abstract view of one subsystem to the other interacting subsystem.
- 6. The use of a ComBlock imposes a structured design methodology by mean of an explicit separation of the work in the uP and FPGA domains.
- 7. The implicit *ComBlock* strategy could simplify concrete Hardware/Software partitioning and implementation of complex cooperative activities.

Thank you for your attention!
